

Programmes / Cours / Section / Cours

Introduction to the Full Planche

The Full Planche is a static strength move that involves holding your body parallel to the ground. The primary muscles engaged in this movement are the anterior deltoids, biceps, and serratus anterior. The entire body is involved, with many other muscles being activated to stabilize the position.

The Full Planche is an advanced move in the world of calisthenics, but with the right strategies, it is within everyone's reach. More than just a challenge, it is an impressive display of strength and control. The good news? With the proper approach, its accessibility is much greater than you might think. This move isn't just for experts; anyone who commits to progressing with discipline and determination can achieve it.

You don't need to be a top-level athlete to succeed. By following a well-structured program and sticking to progressive steps, you'll be amazed at how quickly you can hold this iconic position. Each step of your progression will strengthen your body, improve your technique, and before long, you'll find yourself mastering the Full Planche!

What you need is consistency and full confidence in your potential. By training with precision, your body will adapt, and this move will become more and more natural. Trust your training, because you're much closer to success than you think. Soon, the Full Planche will be one of your accomplishments, allowing you not only to impress others but also to feel the incredible satisfaction of having mastered this skill.

If you're here, it means you're determined to master the Full Planche, so let's not waste any time!

The muscle groups involved in the full planche.

When working on skills, it is important to understand how they function. First, having a better understanding will help you improve muscle activation, which is crucial when training for strength and control. This will also allow you to enhance your sensations and technical analysis skills, which are essential for self-regulation and planning your training. Below is a general overview of the muscles predominantly involved in the full planche and associated movements. For clarity and relevance, the explanations are intentionally simplified and not detailed to the maximum in order to stay as general as possible.

Here are the main muscles involved and their functions: these muscles are responsible for generating the majority of the strength required to perform a planche and the associated movements.

The anterior and lateral deltoids:

They enable arm abduction and antepulsion, meaning they allow you to raise your arms forward and to the sides. These are medium-sized but powerful muscles, and they are primarily engaged during the planche. In practice, these muscles are responsible for maintaining (and even increasing) the angle between the arms and the torso.

The serratus anterior:

They enable the protraction of the scapulae. In other words, when they contract, the shoulder blades move away from the spine and press against the sides of the torso. Despite their relatively limited strength, the role of these muscles is crucial in a planche. They are responsible for elevating the body in relation to the shoulder line. They work in synergy with the deltoids, making them essential for optimizing strength and maintaining stability during the movement.

The biceps:

These muscles enable arm flexion as well as antepulsion (lifting the arms forward). During a planche, the biceps are particularly useful for avoiding "joint rest" at the elbows. Their function in antepulsion (lifting the arms in front) also helps maintain the angle between the arms and torso during planche work. Their involvement is heightened when working in supination, as they align with the direction of resistance. While the biceps are not extremely large or powerful muscles, they are essential for control and stability. However, caution should be taken to avoid overtraining them, as they are not built for excessive strain.

The forearms:

The term "forearms," when discussing the planche, primarily refers to the finger flexors. These muscles are particularly important for maintaining a strong grip and limiting forward collapse. Although their role in overall strength is secondary, they are essential for proper execution of the planche. Indeed, your hands are the only point of contact with the support, from which your entire body must maintain stability. Without a solid grip, it would be difficult to control the position and hold the planche effectively.

The secondary muscles (quadratus lumborum, erector spinae, abdominals, glutes, quadriceps, etc):

They play a crucial role in maintaining core stability, ensuring perfect alignment of the body. This allows for supporting and elevating the legs while keeping the position parallel to the ground during the execution of the full planche.

To summarize and clarify what is most engaged during the full planche, the primary muscles involved are the anterior and lateral deltoids, which account for about 80% of the effort required to maintain the position. The other muscles provide support: the serratus anterior contributes around 10% of the total strength, while the biceps and forearms each contribute about 5%. Finally, the secondary muscles complete the effort, also representing 5% of the muscle involvement.

It's important to understand that the anterior and lateral deltoids are the most crucial muscles in this figure. However, it is normal not to feel them immediately, just like with the other muscles, especially in the beginning. This is not a major issue. The key is to focus on doing your best to feel these muscle contractions. With practice and repetition of the movements, you will gradually develop better muscle connection and be able to feel these muscles working more precisely.

Mindset and Visualization

Mindset and Visualization in Learning the Full Planche

Mastering the full planche is not solely about physical strength. The mental aspect, through mindset and visualization, plays a crucial role in your progress. Developing the right mental attitude can often make the difference between stagnation in training and successfully achieving this skill.

Mindset: Patience and Discipline

Learning the full planche requires time, perseverance, and a progressive approach. It is essential to adopt a mindset focused on patience and discipline. The path to mastering the full planche is long and filled with challenges, but every small victory whether it's holding an intermediate position for longer or feeling better muscle activation is part of the process.

Rather than focusing solely on the final goal, it's important to celebrate every progression. A mindset of success is built on confidence in your abilities, even during phases when results seem slow. Perseverance will help you overcome obstacles, and will push you to stick to your training and stay consistent in your efforts.

Visualization: Anticipating the Movement

Visualization is a powerful tool to accelerate the technical learning of the full planche. Even before physically performing the movement, you can begin to master it mentally. Visualizing your body executing the full planche perfectly, with a straight line, arms extended, and the body parallel to the ground, helps your brain become familiar with the technique and the necessary tension.

By regularly focusing on this visualization, you train your brain to understand the sensations and requirements of the movement. This can help you better recruit muscles and synchronize your body once you move to actual practice. Visualization also acts as a form of mental repetition, allowing you to train even when you're not physically at the bar.

Balance Between Body and Mind

Mindset and visualization work together to create a balance between the body and mind. Adopting a positive mental approach helps you stay motivated during intense training periods and overcome the frustrations that come with the difficulty of the full planche. At the same time, visualization deepens your understanding of the movement and optimizes each training session.

By combining a strong mindset with effective visualization, you significantly increase your chances of mastering the full planche. Not only will this allow you to progress more quickly, but it will also strengthen your long-term commitment, providing the mental endurance needed to reach your goal.

Believe in What You Do

It's crucial to believe in what you're doing. To strengthen this conviction, start by setting simple and achievable short-term goals. These goals should be realistic, motivating, and help reinforce your confidence. Don't just focus on long-term results, but also on your progress and daily development. It's also important to have confidence in your training and actions. If you find a method ineffective or useless, don't dwell on it. Even the most renowned exercise won't bear fruit if you don't believe in it. On the other hand, what you do with enthusiasm and conviction will be much more effective because believing in your actions makes them even more productive.

As already highlighted, self-confidence is a key to success. To build it, you must learn to appreciate yourself as you are. Recognizing your worth and accepting your uniqueness are essential. The ego, when controlled, is not negative. In fact, the more you value yourself, the more convinced you will be of your success.

It's essential to appreciate every action you take. Your mind is influenced by your emotions, which is why it's important to find joy in what you do. Choose movements, methods, or workouts you enjoy and trust in. Get to know yourself well enough to integrate elements that motivate you into your practice. Training should never feel like a burden if you truly want to progress. If what you're doing doesn't align with your deeper desires, it will be counterproductive. Also, consider stepping out of your routine to avoid boredom. Fun or relaxing training sessions can help you refresh your motivation. If you feel your routine becoming monotonous, don't hesitate to adjust it to regain pleasure and energy.

Embrace Challenges

To progress, it's important to step out of your comfort zone. Challenges allow you to push your limits and explore new capabilities. By confronting difficult situations, you not only strengthen your body but also your mind. Every obstacle overcome becomes a personal victory that boosts your self-confidence. However, choose challenges that are realistic and suited to your level to avoid discouragement. Patience is key: every bit of progress, no matter how small, matters. Focus on the effort, not just the outcome.

Be Consistent

Consistency is the key to sustained progress. It's not about training intensely once in a while, but rather maintaining a solid routine over the long term. Consistency allows you to solidify your gains and continue moving forward without regressing. Plan training sessions that fit your lifestyle and stick to them as much as possible. If one day you don't have the energy for a full session, opt for a light workout instead of abandoning it altogether. The most important thing is to stay on track.

Be Kind to Yourself

The path to success is rarely linear. You will experience ups and downs, times when progress seems stagnant, or even regressing. Know that stagnation is part of the learning process, and everyone faces it at some point. Even the best athletes in the world go through phases of stagnation, myself included. Don't be too hard on yourself during these moments. Remember that every difficulty is an opportunity to learn and grow. If you remain patient and persistent, the results will eventually come. Appreciate the journey you're on, and remember that discipline and consistency will take you farther than any fleeting motivation.

Warm-Up

Warming up is an essential part of any workout, crucial for preparing your body for physical exertion. Done at the beginning of your session, it helps you get physically and mentally ready to maximize your performance. Here are the main benefits of a proper warm-up:

- **Increase in body temperature:** By raising your temperature, you dilate the capillaries, facilitating the chemical reactions that produce energy.
- **Better blood flow to muscles:** A higher heart rate allows more blood, and thus more oxygen and nutrients, to be delivered to your muscles.
- **Lubrication of joints:** The production of synovial fluid improves joint movement, reducing friction and optimizing your range of motion.
- **Reduction in muscle stiffness:** By warming up your muscles, you help break down myosin bridges, thereby reducing tension and stiffness.
- **Improved muscle elasticity:** With the increase in temperature, your muscles become more flexible and less viscous, making movements smoother.
- **Better nerve transmission:** Your nervous system functions optimally around 38-39°C, enabling a quicker and more precise response from your muscles.
- **Increased focus:** The warm-up allows you to transition from your day to your workout, gradually sharpening your focus.

All of these processes combined make you more efficient and significantly reduce the risk of injury.

Of course, there are many ways to warm up, but your warm-up should be personalized according to your needs and adapted to your goals. Whatever method you choose, it's important to adhere to these four principles:

1. **Personalization:** The warm-up should meet the specific needs of your body.
2. **Timeliness:** It should be tailored to the time and context of your workout.
3. **Effectiveness:** It should get you in a condition to perform well.

4. **Safety:** It should prevent injuries, not cause them.

Feel free to adjust and incorporate your own warm-up methods to make it the most suitable for you.

Technical Details of the Full Planche

The Hollow Body

The hollow body, or scapular protraction, refers to the action of pushing your shoulder blades outward, using a muscle that's rarely engaged in everyday life, known as the serratus anterior.

A properly executed hollow body is one of the key visual and technical elements that determines whether a person has full control over their full planche.

How to Execute It?

To optimally protract, you need to combine the action of pushing the shoulder blades to the side with **scapular depression** (moving the shoulders away from your ears by lowering them). This will result in the upper part of your back (upper traps) having that rounded, engaged look.

When done correctly, you should feel your upper traps fully stretched and tense.

To be more specific, you should feel as if you're pushing your sternum and the point between your collarbones inward. This action will significantly deactivate the pectoral muscles. The deltoids should become the primary muscles engaged to perform a quality planche. Additionally, you should feel your lats contract as you lower your shoulders, which will automatically engage the serratus anterior.

It can also be performed with a slight thoracic flexion to reduce the lever arm and thus optimize the height of the movement.

Of course, do not overdo this movement, as it can negatively impact the quality of your planche and could potentially lead to dangerous tensions, especially in the cervical spine.

The **hollow body** is simply an optimization to improve your performance. It's difficult to achieve good scapular protraction when you're a beginner, but at an advanced level, it will bring numerous benefits.

A **planche** is a pushing movement, so we must push against gravity. It makes sense to want to be as high as possible. This positioning is the most functional for performing long combinations or holds. Achieving better height and correct protraction will improve the following movements:

1. Your Hold

- The higher you are when executing your planche, the longer gravity will take to pull you down. Being high in your planche reduces the rate at which you fall, allowing you to hold the position longer.

2. Your Press

- Being high with a slight thoracic flexion will help you reach the handstand position more quickly and, most importantly, engage your deltoids more effectively.

3. Your Push-ups

- The hollow body is crucial for performing push-ups optimally. The descent trajectory is somewhat complex, but it is actually logical. The more you manage to descend while maintaining some protraction, the easier it will be to push back up. This helps you rise higher with greater ease and allows you to chain movements more smoothly, such as in combination sequences.

In Summary, The **hollow body** or **scapular protraction** is essential for being high, enduring longer, and performing dynamic strength movements more effectively. Height is the key if you want to perform with endurance, but the hollow body is not the only factor that helps gain height. It's a crucial element in developing overall performance, but it works in conjunction with other factors like strength, technique, and muscle engagement.

The Pelvis (Pelvic Retroversion)

During the execution of a planche, the pelvis must be positioned in **retroversion**. This means that your pelvis rotates forward, which results in the contraction of the glute muscles. This is one of the factors that makes the planche a strict position to perform. In addition to increasing your lever arm by extending your body, you must find the right balance between having your pelvis too tucked and just enough retroversion. Excellent proprioception is required to perfect your positioning. There are two valid and correct pelvic positions:

- **Slight Lumbar Depression:** This will create a slight curve in your planche.
- **Neutral Lumbar Position:** The lumbar region remains neutral, without excessive arching.

What to Avoid:

The pelvis should **not** be in **anterior tilt** (anteversion). This would excessively arch the lower back and push the hips out, resulting in poor body alignment and technically incorrect planche form.

However, **do not over exaggerate** the retroversion of the pelvis, as this can negatively affect the aesthetics of the full planche and make it harder to maintain the position correctly.

The Head / Gaze

The positioning of your head and gaze is crucial, especially for trajectory control. You should avoid tilting your head too far back or tucking it too much, as this could create unnecessary tension in the cervical spine.

Your gaze during the planche should be oriented at about a 30° angle. This seems to be the best compromise, both for the positioning of the **hollow body** and to minimize neck tension.

The Hands / Grip

The grip is an important factor that should not be overlooked, as it can drastically improve your planche.

Parallel Bars:

On parallel bars, it is preferable to keep your wrists aligned and try to minimize lifting the back of your hands. The goal is to maintain as much surface contact with the bar as possible.

If you have the appropriate mobility, this grip will be the most optimal. Staying aligned and maintaining good contact will allow you to be higher and more airy in your planche, leading to better energy transfer and more effective control in dynamic movements like push-ups, presses, or transitions.

If you have mobility issues, you can slightly bend your wrists inward, as long as you feel comfortable and don't experience pain. It's up to you whether you want to work on improving your mobility alongside your training to greatly optimize your performance.

Important Note: Don't forget to **grip the bars tightly** to maintain maximum contact and apply a strong force intention. Actively contract your forearms, shoulders, and biceps much more intensely. This will help you maintain control, improve stability, and optimize your performance during the planche.

Ground:

The ground requires more control than parallel bars. This support doesn't allow you to rely on an external surface for assistance in case you lose control or balance. However, if you have excellent mobility, the force required for the same effort is relatively similar to that on parallel bars.

Of course, this will depend on practice. The more time you spend on one type of support, the easier it will feel compared to others.

There are approximately 4 different hand positions you can vary depending on your preferences and/or mobility issues:

Pronation Grip:

Neutral Grip:

Fake Supination Grip:

Supination Grip:

On a Pull-Up Bar:

The supinated grip on a pull-up bar is quite subtle. You can keep your hands completely aligned, which will place more tension on your biceps. If you're lacking some mobility, you can also make a slight rotation, as if holding bars at a 45° angle, which will make the movement easier. It's a fine nuance, but you will definitely feel the difference when you apply this technique.

Just like on parallel bars, the **contact surface** is extremely important. You must ensure that the fleshy part of your thumb is in full contact. Focus on this point if you want to optimize your height and reduce the risk of falling forward when working in supination.

In **pronation**, mobility plays a significant role once again. This position can be quite hard on the wrists, but also on the shoulders. The muscle fibers targeted for this variation are very different from those used on parallel bars or in supination. I generally feel more comfortable with these two grips than in pronation, as the internal rotation of the radius and ulna is not as natural as a neutral or external rotation position, especially when such intense stress is applied.

ABS ABSORB AND STOMACH ABSORB

This is more of an aesthetic detail than a technical one, but the stomach should be flat during the execution of a full planche. You shouldn't suck it in (stomach absorb) or do anything that would break the symmetry with your lower back.

Having poor abdominal contraction won't drastically change performance, but a natural contraction will help you better control your breathing and your air column. To better understand the contraction, think about what happens when you laugh. That's the sensation you should aim to achieve when holding the planche.

THE ARMS

The arms should be fully extended or controlled. Some people may have hyperlaxity at the elbows, in which case it may be wise not to collapse into the joint's end range to avoid damaging the joint in the long term.

If you have trouble fully extending or locking your arms, one tip is to perform an external rotation of the arm, which means turning the inside of your elbow forward. By making this effort, it will be anatomically more difficult for your arm to bend to the side.

The angle of your arms in a full planche should be about 45 degrees between your wrists and shoulders to optimize your center of gravity, which is located in the middle of your body. This angle helps you find the ideal balance: not too far back, not too far forward. If you lean too far forward, you'll risk performing what's called a "dead planche," which is not optimal because it limits the height of your planche. And height is a key factor in a planche: the higher you are, the more comfortable you'll be maintaining holds, performing push-ups, or completing presses. So, make sure to respect this 45-degree angle to maximize your performance.

At first, it's normal to feel like your body leans too far forward. This simply means you're still building the necessary muscle strength. With regular practice and increased strength, you'll notice progress: you'll gain more height, reduce the angle of your arms, and achieve a proper lever.

ARM SPACING IN A PLANCHE

The spacing between the parallel bars plays a crucial role in proper positioning and comfort during a planche. If the bars are fixed and anchored to the floor, it might be impossible to adjust their width. However, if you're using movable bars, I recommend setting them to a distance equal to the width of your shoulders. Avoid having the bars too close or too far apart. You can also adjust the spacing slightly, by a few centimeters, depending on what feels most comfortable for you. However, the optimal width is generally the same as the width of your shoulders.

LEG POSITIONING

Leg positioning plays a crucial role in maximizing both the effectiveness and the aesthetics of the movement. It is essential that your legs remain fully locked, meaning perfectly extended throughout the entire figure.

One trick is to imagine that you need to elongate yourself as much as possible. To do this, consciously contract your thighs and calves while visualizing that you are trying to touch something as far away as possible with the tips of your toes.

FEET

The feet are like the final touch of your planche. You should feel yourself elongating and experience the extension to perfect your line. Pointing your toes can also help you extend your legs more effectively in general.

There are different approaches: pointed toes, relaxed feet, or flat feet.

In this program, I recommend pointing your toes to optimize contractions, but you can form your own opinion later by experimenting with the different techniques.

THE OVERALL LINE

The line in a planche is considered valid when the shoulders, hips, knees, and feet are aligned. But that's not all. You must also achieve a minimum of protraction and a retroversion of the pelvis to fully validate your movement.

Protraction and a neutral pelvis position don't mean the planche is invalid, but they won't allow you to optimize your performance.

On the other hand, excessive retraction will make the planche invalid, even if the line appears visually correct.

As you've understood, your planche form should be a straight line from your head to your feet. The most important element is incorporating the notion of "stretching" as much as possible while performing your planche. Imagine that your head is reaching to look 30 degrees ahead of you, as far as possible, and do the same with your toes, imagining that they are stretching as far back as they can.

Important note: It's crucial to be aware of all these necessary elements to master the full planche, but at the beginning of learning this movement, it's not necessary to focus on every detail at once. You will likely find it difficult to apply all of these adjustments right from the start. This is why it's important to train at your own pace, and the more you gain control of the movement, the more you can gradually integrate these technical aspects to achieve perfect full planche form.

When trying to correct your full planche form, it's essential to proceed step by step, focusing on one element at a time. Trying to correct every detail simultaneously can be counterproductive, as your body may not be able to absorb all these adjustments at once.

The best approach is to prioritize corrections in a logical order, from the most fundamental to the more subtle. Here's a recommended progression:

1. **Arm locking and correct grip positioning:** Start by ensuring your arms are fully extended and locked, and that your grip is correct to maximize stability.
2. **Head positioning:** Make sure your head is aligned with the rest of your body, avoiding tilting it too much or letting it fall.
3. **Leg tension in the planche:** Make sure your legs are fully extended and aligned with your body to maintain a solid, straight posture.
4. **Scapular protraction or hollow body:** Work on scapular protraction to increase the height of your full planche and improve the aesthetics of the position.
5. **Pelvic retroversion:** Finish by adjusting your pelvis, performing a retroversion to ensure your line is perfect.

By following this chronological method, you allow your body the time it needs to integrate each correction sustainably, while progressing efficiently toward a perfect full planche form.

The Different Exercises to Unlock the Full Planche

Before you dive into the training program, I will introduce you to all the exercises that helped me strengthen my body, and which, in my opinion, are the most effective for your progression toward mastering the full planche. These are the same exercises that I've integrated into my own training. You will also use them in the programs I offer, in order to strengthen your body and bring you closer to mastering the full planche.

It's essential that you thoroughly understand each exercise you will be performing in the coming weeks. I will therefore show you the exercises through videos.

Here is also a PDF link to download the exercises:

Progressive Training Programs

Now is the time to start your first full planche training sessions! If you're here, it means you can already do at least 10 push-ups, which provides a great foundation to tackle this movement.

I will offer you a progressive training program designed to help you move forward step by step. You will find 5 levels of difficulty, allowing you to progress with confidence and challenge yourself as you go.

These training formats are examples that you can adjust to your own sessions. You don't have to follow them strictly. If you want to add or remove elements, feel free to do so. What matters is that at the end of each session, you feel like you've given your best and that you are exhausted from the training. You can also incorporate other skills without affecting your progress. When you feel comfortable with a level and your body has adapted to the program, don't hesitate to move on to the next level to break the routine and challenge your body to reach a new milestone. Generally, I recommend progressing to the next level every 2 to 4 weeks, depending on your progress. By following this training approach, you should be able to master the full planche in about 3 to 5 months.

It's also important to include training sessions based on "feeling," where you don't have to strictly follow a personalized program. These sessions allow you to focus on the cleanliness of your movements, try out new variations to assess your level, or simply do resistance training with a band if you're not feeling particularly strong on that day.

This type of training offers a more flexible approach, ideal for listening to your body. It also serves as a good way to recover between higher-volume sessions planned in your program. By alternating between structured sessions and these more intuitive workouts, you can progress while avoiding burnout.

You can manage your rest days however you feel. I prefer not to impose specific days, as you might miss a good session if the rest is forced. Plus, if you have obligations or unexpected events, it's important to be able to adapt. We all have things to manage in our lives. Know that training about 3 times a week is already excellent. There's no need to train 6 days a week. What matters most is the quality of each session and the energy you put into it, rather than the quantity.

To give you a base and help you structure your training throughout the week, here are two examples of weekly planning that you can follow depending on your energy level: one week with low intensity and one with high intensity. This will allow you to adjust your work to your physical state while maintaining consistent progress:

WEEKLY FULL PLANCHE WORKOUTS

	MONDAY	TUESDAY	WEDNESDAY	THURSDAY	FRIDAY	SATURDAY	SUNDAY
HIGH-INTENSITY WEEK EXAMPLE	COMBO METHOD	DROPSET METHOD	REST	COMBO METHOD	FEELING WORKOUT	DROPSET METHOD	REST
LOW-INTENSITY WEEK EXAMPLE	COMBO METHOD	REST	FEELING WORKOUT	REST	DROPSET METHOD	REST	REST

The program is based on two different training methods, along with a muscle strengthening section at the end of the session, which you can alternate based on your feelings. The goal is to complete the full session using either the combo method or the dropset method once per day, without combining the two methods in the same day.

Combo Method:

The combo method in calisthenics involves chaining multiple movements or skills together without rest, creating a continuous series. This approach not only helps improve fluidity and endurance but also enhances muscle control and coordination. By integrating transitions between the movements, you maximize the work on different muscle groups while building your capacity to maintain a high level of effort over an extended period. Personally, I use this method in my own training because it pushes me to my limits and improves my performance quickly.

Dropset Method:

The dropset method in calisthenics involves performing an exercise to muscular failure, then immediately reducing the difficulty to continue the set without taking a rest. Unlike weightlifting, where you decrease the weight, in calisthenics, you adjust the difficulty of the movements. For example, after reaching failure in a difficult skill like the front lever, you would switch to an easier version, such as the tuck front lever, and continue until exhaustion. The dropset method allows you to maximize time under tension, promoting deep muscle fatigue and accelerating strength and endurance progression. It's a highly effective technique for overloading the muscles and achieving faster gains while staying within the bodyweight training paradigm.

Muscle Strengthening Section:

This section aims to increase the volume of your session, as well as improve the trajectories and form of your movements. You can use resistance bands only if you're unable to handle your own bodyweight. Personally, at the end of each session, after a 5-10 minute break between the training method and the muscle strengthening section, I implement a strengthening system that helps me solidify my body and develop my endurance further. This section also allows you to focus on the quality of your movements and improve your technique. By integrating this strengthening system into your routine, you can target muscles that need extra attention, thus progressing more effectively. This contributes not only to your overall strength but also to your ability to perform more advanced exercises. Over time, you will notice significant improvements in your endurance and performance in calisthenics movements.

Important Note:At the beginning of each session, it's essential to test a more difficult skill than your current level. This will allow you to assess your progress, begin familiarizing yourself with the more advanced variant, and have a benchmark to test again in future sessions.

For example, if you're holding a tuck planche for 3 seconds, try 3 to 5 attempts of the advanced tuck planche in max hold at the beginning of your session with about 5 minutes of rest between each attempt. Even if you can't hold the position yet, simply attempting the skill will help you integrate it better, strengthen the position, and progress toward holding it longer in future sessions. Don't be afraid to experiment at the start of your session, as this is an ideal moment when you're fresh and ready to give your maximum effort.

[Conditions Générales de Vente](#)

[Politique de confidentialité](#)

PROGRAM LEVEL 1
COMBO METHOD

NUMBER OF SETS	COMBOS	REST TIME
X1	LEAN PLANCHE 2S - PIKE PUSH UP TO POSITION LEAN PLANCHE - PIKE PUSH UP X5	3-5 MINUTES
X1	HANDSTAND PUSH UP - LEAN PLANCHE 2S - PUSH UP X3 - LEAN PLANCHE MAX HOLD	3-5 MINUTES
X1	LEAN PLANCHE PUSH UP X2 - PIKE PUSH UP X2 TO POSITION LEAN - MAX PUSH UP	3-5 MINUTES
X1	PIKE PUSH UP X3 - LEAN PLANCHE PUSH UP X2 - LEAN PLANCHE MAX HOLD	3-5 MINUTES
X1	LEAN PLANCHE 2S - LEAN PLANCHE PUSH UP X4 - MAX HANDSTAND PUSH UP	3-5 MINUTES
X1	PUSH UP X5 - PIKE PUSH UP X3 - LEAN PLANCHE MAX HOLD	3-5 MINUTES
X1	PIKE PUSH UP TO POSITION LEAN X3 - LEAN PLANCHE PUSH UP X2 - LEAN PLANCHE 2S - MAX LEAN PLANCHE PUSH UP	3-5 MINUTES

Based on your energy level, perform between 5 and 10 combos. The order doesn't matter choose the ones you prefer. You can repeat the same combo multiple times or create your own following the same structure.

The goal is to build volume, so perfect form isn't essential, though you should still do your best. If you can't perform a move, modify it by removing or replacing it as needed.

PROGRAM LEVEL 1
MUSCLE STRENGTHENING

Now you’re reaching the end of your session. These optional strengthening exercises are here to complement your training. You don’t have to do them if you feel tired. The goal is to allow you to finish your session by going to failure.

NUMBER OF SETS	EXERCISES	REST TIME
X3	TUCK PLANCHE HOLD 5S	5 MINUTES
X3	MAX LEAN PLANCHE PUSH UP	5 MINUTES
X3	MAX LEAN PLANCHE HOLD	5 MINUTES

Adjust the difficulty by using resistance bands (light/medium/heavy) or body weight. You can complete all exercises or focus on 1 or 2 specific areas, depending on your needs (weak points and goals).

PROGRAM LEVEL 2
COMBO METHOD

NUMBER OF SETS	COMBOS	REST TIME
X1	NEGATIVE TUCK PLANCHE X2 - TUCK PLANCHE 2S - LEAN PLANCHE PUSH UP X2 - TUCK PLANCHE MAX HOLD	3-5 MINUTES
X1	TUCK PLANCHE PUSH UP X2 - LSIT TO TUCK PLANCHE - TUCK PLANCHE PUSH UP - MAX PLANCHE LEAN PUSH UP	3-5 MINUTES
X1	ADVANCED TUCK PLANCHE NON HOLD - TUCK PLANCHE PRESS - NEGATIVE TUCK PLANCHE - MAX TUCK PLANCHE PUSH UP	3-5 MINUTES
X1	SEMI PLANCHE TO TUCK PLANCHE PUSH UP - HANDSTAND PUSH UP X3 - TUCK PLANCHE PUSH UP X2 TO MAX HOLD TUCK PLANCHE	3-5 MINUTES
X1	LSIT TO TUCK PLANCHE - TUCK PLANCHE PRESS - NEGATIVE TUCK PLANCHE - LSIT TO TUCK PLANCHE MAX HOLD	3-5 MINUTES
X1	TUCK PLANCHE PUSH UP X4 - LSIT TO TUCK PLANCHE - TUCK PLANCHE PUSH UP -TUCK PLANCHE TO LEAN PLANCHE - MAX LEAN PLANCHE PUSH UP	3-5 MINUTES
X1	HANDSTAND PUSH UP X5 - NEGATIVE TUCK PLANCHE - LSIT TO TUCK PLANCHE MAX HOLD - MAX HOLD LEAN PLANCHE	3-5 MINUTES

Based on your energy level, perform between 5 and 10 combos. The order doesn't matter choose the ones you prefer. You can repeat the same combo multiple times or create your own following the same structure.

The goal is to build volume, so perfect form isn't essential, though you should still do your best. If you can't perform a move, modify it by removing or replacing it as needed.

PROGRAM LEVEL 2
MUSCLE STRENGTHENING

Now you're reaching the end of your session. These optional strengthening exercises are here to complement your training. You don't have to do them if you feel tired. The goal is to allow you to finish your session by going to failure.

NUMBER OF SETS	EXERCISES	REST TIME
X3	MAX HOLD ADVANCED TUCK PLANCHE	5 MINUTES
X3	MAX ADVANCED TUCK PLANCHE PUSH UP	5 MINUTES
X3	MAX TUCK PLANCHE PRESS	5 MINUTES

Adjust the difficulty by using resistance bands (light/medium/heavy) or body weight. You can complete all exercises or focus on 1 or 2 specific areas, depending on your needs (weak points and goals).

PROGRAM LEVEL 3
COMBO METHOD

NUMBER OF SETS	COMBOS	REST TIME

X3	MAX STRADDLE PLANCHE PRESS	5 MINUTES

Adjust the difficulty by using resistance bands (light/medium/heavy) or body weight. You can complete all exercises or focus on 1 or 2 specific areas, depending on your needs (weak points and goals).

My Practical Tips for the Full Planche

The Different Starting Positions for the Full Planche

To optimize your full planche, there are several starting techniques. Here's an explanation of the main starts, their benefits, and how to choose them based on your goals:

The Lean Planche Start

In my opinion, this is the most optimal start for working on the proper contractions and muscle activations necessary when lifting your planche. By focusing on a well-executed lean planche, you encourage a better form when lifting your planche.

However, it can be difficult to master if you spend too much time in the lean planche, as you risk losing energy. Additionally, if you still lack strength, it can be challenging to lift your legs.

Recommendation: This start is ideal if you want to focus on your planche form and the right muscle activations.

The Tuck Planche to Full Planche Start

This start is useful if you're looking to gradually adjust the difficulty. Starting from a high tuck planche, you can unfold your legs to control the descent, thus maintaining a longer hold time.

However, this start can be challenging for proprioception: it's not always easy, at first, to visualize yourself correctly in space while unfolding your legs with proper form. Adjusting your posture can also be difficult.

Recommendation: This start is perfect for working on a prolonged hold in your full planche.

The Jump to Full Planche Start

Less common, this start uses the momentum of your legs to gain height before entering the full planche. It can be useful for engaging a good hold afterward, but like the tuck start, managing proprioception can be challenging.

Recommendation: This start is interesting if you're looking to experiment with a different method to gain more initial height.

The choice of start depends on your goals:

- If you want to work on the form of your full planche, the lean planche start is the most suitable.
- If you want to maximize your hold time, the tuck planche to full planche start is more appropriate.

However, it is important to vary the starts to develop different muscle activations and gain a better understanding of your body in space. Over time and with experience, you will become comfortable with any start and be able to adapt them to your needs.

The Equipment:

The Bars:

The bars and the surface on which you perform your movements come with certain constraints that can impact your performance. Unfortunately, we don't always have control over where we train, and sometimes we can't modify certain factors that may hinder our practice.

It's essential to train on a surface that is tailored to you, your mobility, hand size, range of motion, and any discomforts you may have. If you're able to optimize these factors, it can make a huge difference. You'll improve your performance while reducing recurring discomfort or pain.

Grip and Magnesium:

We all know the benefits of magnesium, which helps eliminate the effects of moisture, such as sweat or clammy hands. It's a vital tool for performance, preventing grip loss that could disrupt your movement. Be cautious about the amount you use, as too much magnesium can have the opposite effect, making the surface slippery due to the powdery residue.

Adding grip tape or anti-sweat grip on your bars, found in sports stores in the tennis or badminton section, is optional. However, it can drastically enhance your performance by improving your grip.

If your parallettes seem too thin or suboptimal, adding grip will allow you to adjust the thickness to your preference, improving your grip and strength transfer. For movements like the full planche, having a secure grip on the bars is crucial for stability and control. Grip tape thickens the handles, optimizing your hold and reducing muscle fatigue, allowing you to perform advanced variations with more control.

That said, you should learn to adapt to different circumstances. In some parks or competitions, you might not have the ideal setup. No matter the situation—whether advantageous or not—it's important to adapt and still perform at your best.

Shoes:

Wearing shoes can have the disadvantage of increasing the leverage on your body by adding weight to the end of your limbs. This makes your movements harder to hold. If you want to perform optimally, consider taking your shoes off.

However, they can also serve as a way to intensify your workout, almost like adding weight or resistance to your movements.

Resistance Bands:

Using resistance bands in calisthenics can be both helpful and counterproductive if overused. Placing the band under your hips can assist in lifting some of your body weight, making the movement easier. This is particularly useful at the end of a session to better understand muscle activations and continue strengthening even when you're fatigued.

That said, it's important not to rely too much on resistance bands. If your body becomes too accustomed to this support, it may hinder your progress, as you won't be working at full intensity without assistance.

Breathing:

Breathing, though often overlooked in our field, is a crucial parameter to master if you want to perform at a high level. It's essential in many physical practices, and even more so in bodyweight strength training. It's important to distinguish between strength (short, intense efforts) and strength endurance (long, high-volume efforts).

Of course, when you're starting out, controlling your breathing will be difficult, or even impossible. Your main concern will be holding a skill for one or two seconds or completing a rep or two. This high intensity naturally leads to breath-holding, which generates a more powerful global bracing of the body.

However, becoming aware as early as possible that, with time, you can learn to control your breathing will only benefit you.

The stronger you get in a movement, the more natural it will feel, and the more easily you'll be able to breathe while performing it. For example, when you first start hand balancing, your head is upside down, and you're in total breath-holding mode. But as you gain experience, you realize it becomes as simple as standing on your feet—you can talk, breathe, even laugh. The same applies to strength-based movements. The stronger you become, the less you'll need to focus on breathing because the movement will feel so easy.

Intention in Calisthenics:

No matter the discipline, intention is crucial for optimizing your performance. It involves truly focusing and prioritizing a technical detail or muscle contraction to facilitate or enhance the action you're performing.

Intention will be one of the keys to your progress, whether it's in gaining strength, improving technique, or increasing speed. Of course, all three are closely interconnected, but each factor has its own importance.

Intention for Strength:

When we're comfortable with a movement, we tend to exert less force because the movement has become relatively natural. We can intentionally relax and conserve energy, which is great.

But sometimes, when performance is the main goal, it's useful to understand the concept of voluntary contraction. Voluntarily contracting certain muscles harder to optimize various parameters, such as the height of the movement, time under tension, bracing a specific area during dynamic strength movements, grip, and more. There are many instances where saying "contract harder" before or during a movement will only benefit your performance.

Intention for Technique:

When facing a technical issue, improving your intentionality is crucial. No matter the movement or where your weakness lies, it's always better to focus on having the correct contractions and proper positions.

For example, if your back in the full planche is in complete retraction and you want to fix it and move towards protraction, even if your initial attempts to apply protraction don't show results, the mere act of performing the correct contractions and aiming to engage the right muscle groups will put you on the right path. This intention will only help improve technical details like this, so don't neglect neuromuscular connection.

Intention for Speed:

Being explosive, quick, and fluid is not just a matter of genetics or muscle strength. A large part of your explosiveness in dynamic strength movements, such as full planche push-ups, presses, etc., will be closely linked to the speed intent you have during their execution.

Voluntary Contraction:

Voluntary contraction is quite similar to intention, but it focuses even more on the muscular side. It involves consciously contracting certain areas more strongly overall or targeting a specific muscle to develop more strength and engage more fibers. When we're comfortable with a movement, we may tend to not push ourselves too hard, but consciously contracting the targeted areas will optimize the effort. If you want to improve your form, hold time, execution speed, etc., this is a factor not to be overlooked.

Voluntary contraction can simply be summarized as an increased level of focus.

Film Yourself:

Filming yourself in calisthenics is a valuable tool for progress. It allows you to see exactly how you execute each movement and detect mistakes you might not notice during training. By watching the video, you can analyze your posture, alignment, and transitions, and correct the details that might be hindering your progress. It's also a great way to track your progress over time and measure improvements. Learning to self-analyze makes you more autonomous in your training, as you become capable of identifying what works well and what needs adjustment to reach the next level.

Frequently Asked Questions

I will now answer the most frequently asked questions to help you become fully independent during your training sessions and optimize your performance to the maximum.

Do I absolutely need to master the handstand to learn the full planche?

No, you don't need to master the handstand to succeed at the full planche. That's actually why I haven't included handstand training in this program. Although some exercises, like handstand push-ups, are included, they should be done against a wall to work on strength without needing balance.

However, it's recommended to work on the handstand alongside your training, especially if you're aiming for variations like presses where handstand mastery becomes essential. The exercises in this program will significantly strengthen the muscles required for handstand training, and then you'll just need to focus on balance and technique to master it.

You can incorporate handstand exercises at the end of your sessions to develop this additional skill. Over time, by practicing movements like the tuck planche presses or straddle planche, you'll naturally unlock the handstand.

How much time should I train per day and per week to get good results?

The duration of your training depends on several personal factors: your endurance level, recovery ability, and rest times. If your breaks are long, this will naturally extend the session. However, there is no fixed duration to follow. A 30-minute session can be more productive than a 2-hour workout if it is well-structured. The quality of the training is always more important than the quantity.

As for the number of sessions per week, that's also variable. Some people progress very well with 3 training sessions per week, while others prefer 6 or 7. What matters is listening to your body and adjusting based on what works for you.

I recommend starting gently with 3 sessions per week, each lasting between 30 minutes to 1 hour. Gradually increase the frequency and duration over the weeks to allow your body to adapt effectively.

Should I continue doing basic exercises like push-ups once I can hold the tuck planche?

Once you've mastered the tuck planche, you don't have to continue doing basic exercises like push-ups, unless you enjoy those movements or want to set specific goals in that area. Basic exercises are helpful for strengthening your body, but it's crucial to understand that it's the specificity and repetition of a movement that allow you to master it.

For example, someone who only does push-ups without ever trying to hold a tuck planche might be able to do 20 push-ups but could struggle to hold a tuck planche. To progress, you need to dare to attempt the movement, integrate it into your workouts, and then repeat it regularly while increasing the intensity. This will allow you to move towards more advanced positions like the advanced tuck planche or straddle planche.

Personally, once I had built a solid foundation and mastered my first planches, I stopped doing push-ups because they were neither a goal nor a priority for me. That didn't prevent me from progressing in planche. So, if your goal is to focus on the planche and its variations, you can reduce or even stop the basics and focus on specific movements.

Should you accept working with "bad form," and when should you correct it?

Although the ultimate goal is to adopt perfect form, working with "bad form" is an essential step and even recommended in some cases. It's important to be aware of this approach: allowing yourself to intentionally degrade your form at the beginning can help you develop endurance and strength. Once these basics are solidified, it will be easier to gradually correct the technique.

Personally, I've often used this method in my training, and I still do today. Working with "bad form" in a controlled manner helped me progress, especially in endurance, and then made me more comfortable with executing a clean technique. So, don't be afraid to incorporate this type of work into your practice, as long as you stay mindful of correcting your form as you progress.

Can I work on the full planche at the same time as other skills, like the front lever?

Yes, it's definitely possible to work on other skills at the same time as your progress with the full planche. However, keep in mind that this might slightly slow down your progress, especially if you're focusing on multiple movements that you haven't mastered yet. You'll still be able to unlock them, but it will take a bit more time.

You have two options: work on multiple skills on the same day or alternate by dedicating a day to each movement. Once you're comfortable with several elements, it can be interesting to combine them into combos, which will enrich your workouts and develop your creativity.

Should you train your legs in calisthenics?

Some people fail to understand that it's not always necessary to train legs. Some focus solely on aesthetics, the visual aspect, and the imbalance between the upper and lower body in certain practitioners. However, it's crucial to understand that for some athletes, the primary goal isn't visual harmony but rather optimization and, above all, performance.

So why criticize a calisthenics practitioner, specialized in strength-based moves, for not having developed legs? It's as absurd as blaming a cyclist for not having big biceps. It serves no purpose for them, and they couldn't care less about their aesthetic appeal to a certain category of uninformed people.

The same applies to us in calisthenics. Training legs would simply be a waste of time considering our objectives. It's also important to understand that legs significantly affect the difficulty of movements and influence your leverage.

It's essential to define your goals: do you want to achieve symmetry, feel good in your body, be well-rounded, or pursue ultimate performance in advanced moves? If your primary goal is performance, then your focus should be exclusively on mastering moves and upper-body training.

How do I know if I'm ready to move on to the next progression?

You'll know you're ready to progress when you feel comfortable with your current training. If the exercise starts to feel easy, it's time to move on to the next step. Don't be afraid to face difficulty — challenging your body is the only way to push past your limits and reach new levels.

Don't hesitate to try variations that seem tough. Failure is an essential part of success: every failed attempt brings you closer to your goal. Personally, I've failed countless times while attempting certain moves, but it's by embracing these challenges that I've mastered them. Step out of your comfort zone, and you'll see results!

Is it beneficial to train with resistance bands?

Resistance bands can be a helpful tool for learning proper movement patterns in certain exercises, like planche push-ups or presses. They can also be useful for adjusting your planche form at the end of a session. However, it's essential not to rely too heavily on them. The goal is to use them as little as possible to avoid becoming dependent.

I recommend incorporating them only at the end of a session to fine-tune your technique. Personally, I've never used resistance bands to unlock my skills, and I've achieved excellent results without them.

What should you do if you're having a "bad day" and can't train?

It's important to understand that "bad days" happen to every athlete, including me. You can't always be at 100% or have the same energy levels, and many external factors can influence this: lack of sleep, bad news, or simply a tough day. Here are two options to manage these moments:

Take a Complete Break:

If, despite your best efforts, you're feeling no positive sensations during training and nothing is working, know that it's completely normal. In this case, you can choose to stop your session entirely and come back stronger in the following days. What matters most is consistency over the long term. One or two forced rest days per month won't negatively impact your progress, as long as it remains an exception and not a habit. This happens to me as well, and I view these breaks as sometimes necessary.

Do a Light Session:

If you still have a little energy left, go for a low-intensity session. Focus on simple and basic exercises to maintain your rhythm without pushing yourself too hard. This allows you to stay active while conserving energy for a more intense session later.

The key is to listen to your body and avoid unnecessary frustration. Progress is built through consistency, not daily perfection.

What should you do if you can't transition from the straddle planche to the full planche?

Transitioning from the straddle planche to the full planche can be challenging, but often, the biggest obstacle is mental. Being so close to your goal can create pressure. It's important to understand that if you can hold a straddle planche for 4 to 5 seconds, there's no need to focus on extending that hold time. At this stage, you should prioritize attempting the full planche at the beginning of your sessions. Start with 5 full planche attempts and then move on to training methods focused on the straddle planche.

The straddle planche and the full planche are distinct skills with different sensations. Your body needs to adapt to the specific position of the full planche, and the only way to achieve that is through repeated practice. Even if, at first, you feel like you're stagnating or failing on every attempt, that's a normal part of the process. Persistence is key — each repetition teaches your body something new.

Go for it without fear, even if you fail repeatedly. It's through numerous attempts that your body will eventually understand the movement, and over time, you'll succeed. Remember: having excellent preparation or perfect conditioning isn't enough if you never attempt the full planche. Personally, I had to go through hundreds of attempts before mastering it, and with consistency, you'll achieve your goal too.

What should you do once you've mastered the full planche?

This program is designed to help you master a 2 to 3-second full planche hold. Once you've achieved this goal, your next challenge will be to solidify your mastery based on your ambitions.

If you want to progress further, you'll need to return to a similar training foundation, creating longer combos on your own and incorporating increasingly difficult variations. These evolutions will push your limits.

Remember, it's crucial to never stay in your comfort zone. Regularly test new training methods and explore new elements to keep progressing and reach a higher level.

Your turn !

You've just acquired the essential knowledge and tools to master the full planche and take your calisthenics practice to an entirely new level. This program has been designed to provide you with clear, effective methods that you can directly apply to your daily training.

Remember: every session is an opportunity to push your limits and get closer to your goals. The key lies in determination, passion, and consistent commitment. If I've reached a world-class performance level, it's not due to luck or extraordinary genetics, but because of hard work, unwavering discipline, and a constant drive to give my best.

You too can adopt this champion mindset: every effort counts, every repetition brings you closer to your dreams. With the right mindset and the tools you now have, nothing can hold you back.

This is your moment! Use this program to perform, progress, and showcase your potential. I would be honored to follow your journey, so be sure to tag me in your Instagram stories so I can see your progress and share your journey with the community.

If any part of the course is unclear or if you have any questions, don't hesitate to send me a message. I'm here to guide you and help you maximize your results.

I wish you spectacular progress, unwavering determination, and all the success you deserve in this demanding yet incredibly rewarding discipline. It's your turn now!
